## Problem 5

You are given a directed graph  $G = (V, E)$  with possibly negative weighted edges.

**(a)** Suppose you know that the shortest path between any two vertices is guaranteed to have **at most**  $k$  edges. Give an algorithm that finds the shortest path between two vertices  $u$  and  $v$  in  $O(k(n + m))$  time.

**(b)** Suppose you know the shortest path from  $u$  to  $v$  contains **exactly**  $k$  edges. Give an algorithm that finds the shortest path between two vertices  $u$  and  $v$  in  $O(k(n + m))$  time. The path need not be simple.

## Solution

### (a)

*Intuition.* Assume the path runs from  $u$  to  $v$ . We run the Bellman-Ford algorithm for  $k$  rounds, and then backtrack to find the distance of  $v$  from  $u$ .

To be more specific, we use a modified version of BFS to traverse all the nodes within  $k$  steps from  $u$ .

---

*Pseudocode.*

- Create a BFS queue, a set `visited`, and a `dist` array initialized with  $\infty$  for all vertices except  $u$
- Add  $u$  to `queue` and mark it as `visited`
- Initialize an iteration counter
- While `queue` is not empty AND counter is less than  $k$ 
  - Dequeue a vertex  $w$  from `queue`
  - For each vertex  $x$  **adjacent to  $w$  (Modification to B-F)**
    - $\text{dist}(x) = \min(\text{dist}(x), \text{dist}(w) + \text{weight}(w, x))$
    - If  $\text{dist}(x)$  is updated, make  $w$  the parent of  $x$ 
      - If  $x$  is not `visited`, mark  $x$  as `visited` and add  $x$  to `queue`.
  - Increment the counter
- Among all `visited` nodes, find the node  $v$  and its *distance* from  $u$ .
- Starting at  $v$ , backtrack the parents until we reach  $u$ , adding nodes along the way to the *path* in reverse order.

---

Time complexity of this modified BFS algorithm is  $O(k(n + m))$ , as it iterates at most  $k$  times, and each iteration processes all  $n$  vertices and  $m$  edges in the worst case.

### (b)

Same as part A. We find the distance and path of  $u \rightarrow v$  after exactly  $k$  rounds of Bellman-Ford.
